We report enhanced sensitization of silicon through nonradiative energy transfer (NRET) of the excitons in an energy-gradient structure composed of a cascaded bilayer of green- and red-emitting CdTe quantum dots (QDs) on bulk silicon. Here NRET dynamics were systematically investigated comparatively for the cascaded energy-gradient and mono-dispersed QD structures at room temperature. We show experimentally that NRET from the QD layer into silicon is enhanced by 40% in the case of an energy-gradient cascaded structure as compared to the mono-dispersed structures, which is in agreement with the theoretical analysis based on the excited state population-depopulation dynamics of the QDs. © 2013 AIP Publishing LLC. [http://dx.doi.org/10.1063/1.4858384]

Energy conversion efficiency is of great importance in light-harvesting systems including silicon (Si) based photovoltaic solar cells.1 For energy conversion, utilization of the optical spectrum by Si is limited due to being an indirect bandgap semiconductor. Previously, in order to enhance optical absorption of bulk Si, several techniques have been proposed including light trapping,2 plasmonic field enhancement,3 and external light sensitization.4 For the efficiency enhancement, fluorescent sensitizers of Si using colloidal quantum dots (QDs) have been proposed owing to the tunable optical properties and large absorption cross-section of the QDs. Because of their superior properties, QDs are very promising materials for various optoelectronic applications.5–8 To this end, spectral sensitization of Si via QDs was demonstrated using both radiative and nonradiative energy transfer (NRET). NRET, which relies on the near-field dipole-dipole coupling, is a good candidate of directional energy flow in nanoscale systems.9–12

Previously, a monolayer of single type of QDs was employed to realize nonradiative sensitization of Si.13 Furthermore, it has been recently shown that this type of NRET is phonon-assisted process unlike conventional NRET (or also known as Förster resonance energy transfer) systems of both fluorescent donor and acceptor.14 Since Si is an indirect bandgap material, phonon-assistance is required to realize nonradiative transfer of the excitation energy in the near-field. However, these types of QD-sensitized Si systems were always limited to a single type of QD donor. Alternatively, it has been reported that excitonic energy transfer among the QDs can be boosted using multilayer of QD structures with different sizes, which enables the energy gradient useful for exciton funneling15–17. Using this exciton funneling, photoluminescence enhancement was achieved via inter-QD NRET in an energy-gradient structure.16 Such multi-layered QD solids were also used as an efficient platform for enhanced exciton transfer from an epilaxial quantum well to the gradient-QD bilayer.18 Lee et al. demonstrated a cascaded-NRET scheme to boost the absorption of CdTe nanowires via green and yellow CdTe QDs.19 A remarkable NRET from the outer-layer CdTe QDs into CdTe nanowires using chemical linkers was observed in their structures, resulting in a 4-fold luminescence enhancement of the nanowires. All these results indicate the great potential of these energy-channeling composite systems for the enhancement of exciton population in a luminescent acceptor.

In this study, different from the previous reports, we propose and demonstrate enhanced sensitization of silicon as a non-luminescent material technologically important for photovoltaics as well as photodetection without any need for using chemical linkers between QDs. To this end, we used the energy-gradient structure composed of a hybrid bilayered construct of green- and red-emitting CdTe QDs (GQDs and RQDs, respectively) on bulk Si. Dynamics of NRET from the QDs into Si (NRETQD→Si) for such a cascaded structure with two types of QDs were investigated and compared to those for the structures with mono-dispersed QDs. Here, we find substantially enhanced NRETQD→Si using Si with the energy-gradient structure as compared to the mono-dispersed QD structures, which suggests the increased exciton population of the QDs closer to Si in the energy-gradient structure. Energy-gradient structure enables the migration of a favorably greater number of excitons from GQDs into RQDs to transfer into Si, which leads to the improved sensitization in addition to enhanced overall NRET efficiency. Resultant significant enhancement of exciton population in Si offers an advantageous route for sensitization of Si via NRET, which was previously limited to mono-dispersed and single monolayer cases.

Herein, CdTe GQDs and RQDs were synthesized with the respective radii of 1.29 and 1.86 nm, according to the procedure reported by Rogach et al.20 We fabricated hybrid nanostructures using layer-by-layer (LBL) deposition technique.
response of the pulsed laser system, the decays were deconvoluted with the instrument response function. TRF decays were analyzed by 1/e fitting and lifetimes were obtained via amplitude-averaging of multi-exponentials ($\chi^2 \sim 1$). Samples (1), (2), and (3) are the references. However, quantum mechanically, a dipole nearby a different refractive index medium alters its radiative recombination dynamics. Therefore, the lifetimes are corrected in the case of quartz references considering the theory by Novotny and Hecht. In the lifetime analysis, NRET rates were calculated using the expression $\gamma_{\text{QD} \rightarrow \text{Si}} = \gamma_{\text{hybrid} \rightarrow \text{Si}} - \gamma_{\text{QD} \rightarrow \text{Si}}$, where $\gamma_{\text{hybrid} \rightarrow \text{Si}} = 1/\tau_{\text{hybrid} \rightarrow \text{Si}}$, is the excited state relaxation rate of either QGDs or RQDs in the hybrid structure and $\gamma_{\text{QD} \rightarrow \text{Si}}$, where there is no NRET into the bulk-substrate. Efficiency of NRET was found using the relation $\eta = \frac{\gamma_{\text{QD} \rightarrow \text{Si}}}{\gamma_{\text{QD} \rightarrow \text{Si}} + \gamma_{\text{QD} \rightarrow \text{Si}} \gamma_{\text{QD} \rightarrow \text{Si}}}$.

Exciton transfer dynamics of QGDs bilayer (GQD/GQD/Si) and cascaded bilayer on Si (GQD/RQD/Si), and quartz groups on quartz (GQD/GQD/quartz and GQD/RQD/quartz) were investigated. As depicted in Fig. 2, we observed faster decays for the GQD/GQD/Si and GQD/RQD/Si samples as compared to their respective control groups, which is an indication of NRET from the QDs into Si. Moreover, NRET efficiency of 20% for the exciton migration from the QDs into Si was calculated by using the lifetimes measured for the GQD/GQD/Si and GQD/GQD/quartz structures at 535 nm. All the TRF lifetimes are presented in Table I. A considerable amount of exciton migration exists from GQD into RQD (with an NRET efficiency of 24%) calculated by using the rates for the GQD/RQD/quartz and GQD/GQD/quartz structures. Furthermore, excitation population inside the QDs decays faster for the GQD/RQD/Si sample as compared to that for the GQD/GQD/Si sample and this indicates an enhanced NRET as a result of the funneling effect in the cascaded structure.

In order to verify the gradient exciton feeding from the cascaded bilayered of differently sized QDs into Si, we further investigated the exciton transfer dynamics of the donor QDs at the RQD emission wavelength in detail. TRF decay curves of RQD/RQD/Si, GQD/RQD/Si and their respective
control groups on quartz substrates are presented in Fig. 3. We obtained NRET\textsubscript{RQD→Si} efficiency of 80\% for the exciton migration from the RQDs into Si by using the lifetimes for the RQD/RQD/Si and RQD/RQD/quartz structures measured at 640 nm (Table I). In the context of gradient energy feeding, we observed an increased RQD lifetime for the cascaded GQD/RQD/Si structure as compared to that for the RQD/RQD/Si sample. This is owing to the strong exciton feeding, we observed an increased RQD lifetime for the cascaded GQD/RQD/Si structure as compared to that for the RQD/RQD/Si and RQD/RQD/quartz structures measured at 640 nm (Table I). in the QD/RQD/Si sample, which has a slower GQD exciton population decay than its cascaded structure (Fig. 2). In this configuration, the TRF lifetime is measured to be 0.363 ns (Table I).

To examine the experimentally observed NRET behaviors, relative exciton populations in Si were calculated using the efficiencies extracted from the TRF rates. The GQD lifetime is shortened down to 0.263 ns in the GQD/RQD/Si structure, while it is measured to be 0.444 ns in the GQD/GQD/quartz structure as the reference sample (Table I). By using these data, we estimate an exciton transfer rate of $\gamma_{\text{NRET}_{\text{GQD→RQD}}} = 1.550 \text{ ns}^{-1}$ and the NRET\textsubscript{GQD→RQD} efficiency is calculated to be around 41\%. Based on this result and NRET\textsubscript{RQD→Si} efficiency (80\%), we found the exciton populations for the GQD/RQD/Si structure (Case 1) and RQD/RQD/Si structure (Case 2). Comparing the population levels with each other, the enhancement factor (Eq. (9), supplementary material\textsuperscript{21}) for the exciton transfer into Si (% of excitons for Case 1—% of excitons for Case 2)/% of excitons for Case 2) was found to be $\sim 40\%$. Moreover, the enhancement factor is $\sim 450\%$ when the exciton population for the GQD/RQD/Si structure is compared with the exciton population for the GQD/GQD/quartz structure. This relatively huge factor probably stems from the efficient use of the trapped excitons in surface states of the GQDs, which have more trap states at the surface resulting from the synthesis process.\textsuperscript{15}

Both of these results ($\sim 40\%$ and $\sim 450\%$) remain approximately the same when we calculate the population for the GQD/RQD/Si structure using NRET\textsubscript{GQD→RQD} efficiency of 24\% and NRET\textsubscript{RQD→Si} efficiency of 80\%.

To further investigate the importance of energy gradient for NRET\textsubscript{QD→Si}, we also analyzed the decay curves from the GQD/GQD/Si sample, which has a slower GQD exciton population decay than its cascaded structure (Fig. 2). In this configuration, the TRF lifetime is measured to be 0.363 ns (Table I). Weaker exciton transfer with a lower rate of $\gamma_{\text{NRET}_{\text{GQD→Si}}} = 0.503 \text{ ns}^{-1}$ is calculated using the GQD/GQD/quartz structure as the reference, and a smaller NRET\textsubscript{GQD→Si} efficiency (18\%) is observed as compared to the energy gradient structure (NRET\textsubscript{GQD→RQD} = 41\%). In the case of employing the cascaded structure, it is therefore possible to boost this exciton funneling owing to the better utilization of the excitons in the QD layer via directed exciton transfer.

Furthermore, a theoretical study was performed to investigate the exciton populations in Si as a result of the NRET\textsubscript{QD→Si} process. For this purpose, we used a model based on density matrix formulation of near-field interactions. The master equations corresponding to the density matrices are derived as

$$\frac{\partial \rho_{AB}}{\partial t} = -\frac{i}{\hbar} [V_{AB}, \rho_{AB}] - \left( \gamma_{1} \gamma_{2} \rho_{AB} + \rho_{AB} \gamma_{2} \right),$$

(1)

$$\frac{\partial \rho_{BC}}{\partial t} = -\frac{i}{\hbar} [V_{BC}, \rho_{BC}] - \left( \gamma_{1} \gamma_{2} \rho_{BC} + \rho_{BC} \gamma_{2} \right) + P_{AB} \rho_{AB},$$

(2)

$$\frac{\partial \rho_{E}}{\partial t} = \left( \gamma_{1} \gamma_{2} \rho_{E} + \rho_{E} \gamma_{2} \right) + P_{BC} \rho_{BC},$$

(3)

where $\rho_{AB}$, $\rho_{BC}$, and $\rho_{E}$ represent the density matrices with the energy level $E_{1}$, $E_{2}$, and $E_{3}$, respectively (Fig. 4(b), inset). Herein, $V_{AB} = \hbar U_{QD_{1}→QD_{2}}$ is the interaction between the levels with energy $E_{2}$ of the top QD layer (QD\textsubscript{1}) and the bottom QD layer (QD\textsubscript{2}); $V_{BC} = \hbar U_{QD_{2}→Si}$ is the interaction between levels with energy $E_{2}$; $\gamma_{1}$, $\gamma_{2}$, and $\gamma_{3}$ are the di-agonal matrices whose diagonal elements are given by $\gamma_{1}$ and $\gamma_{2}$ respectively. $P_{AB}$ represents the relaxation from the energy level $E_{1}$ to $E_{2}$; and $P_{BC}$ represents the relaxation from the energy level $E_{2}$ to $E_{3}$ (see supplementary material\textsuperscript{21} for more details). Excitonic relaxation rates for the GQDs and RQDs were obtained experimentally as $\gamma_{\text{GQD}} = \frac{1}{0.33 \text{ ns}}$ and $\gamma_{\text{RQD}} = \frac{1}{0.36 \text{ ns}}$, and, for Si, it was taken as $\gamma_{\text{Si}} = \frac{1}{444 \text{ ns}}$. The interaction rate between the QDs was taken as $U_{QD_{1}→QD_{2}} = \frac{1}{100 \text{ nm}}$, and $U_{QD_{2}→Si} = \frac{1}{370 \text{ nm}}$, which are reasonable values present in the literature.\textsuperscript{24,25} Finally, for the interaction rate between the QD and Si, we used $U_{QD_{2}→Si} = \frac{1}{437 \text{ nm}}$. Fig. 4(a) shows the exciton population (in %) for the cases.
of: (1) \(GQD \rightarrow RQD \rightarrow Si\); (2) \(RQD \rightarrow RQD \rightarrow Si\); and (3) \(GQD \rightarrow GQD \rightarrow Si\). As it is shown, the best case for exciton transfer is given by Case 1, where the exciton transfer is cascaded from the GQD into the RQD and, at the end, into Si. The worst case corresponds to Case 3, where the exciton is transferred from the GQD in the first layer into the GQD in the second layer and, finally, into Si. The relative decrease in the exciton population for Case 1 with respect to Case 2 ((# of excitons for Case 1—# of excitons for Case 2)/# of excitons for Case 1) is given in Fig. 4(b) as the quenching factor (Eq. 10), supplementary material. The enhancement factor for Case 1 with respect to Case 2 is also depicted in Fig. 4(b). As given in this figure, the enhancement factor reaches up to \(~50\%\) at the steady state condition, which is similar to the aforementioned experimental value of \(40\%\) (more details are given in the supplementary material). All in all, the theoretical model is in good agreement with the experimental results and all these findings offer a strong evidence for the formation of gradient energy transfer, which leads to higher exciton population inside Si.

In summary, we demonstrated strong enhancement in the exciton population transferred into Si using the energy-gradient hybrid structures composed of cascaded bilayered green- and red-emitting QDs on Si. NRET dynamics were investigated for the cascaded structure and the structures with mono-dispersed QDs. For the cascaded architecture, exciton transfer efficiency of \(41\%\) from the GQDs into the RQDs and of \(80\%\) from the RQDs into Si was achieved at room temperature. As compared to the exciton population for the RQD/RQD/Si structure, the enhancement factor of exciton transfer into Si for the cascaded structure was found to be \(~1.4\) (\(40\%\)), which is in good agreement with the theoretical results of \(~1.5\) (\(50\%\)). All these findings suggest that the energy-gradient structures with hybridized QDs on top of Si allow for high efficiency, which can be utilized in photovoltaic, photodetection, and possibly other optoelectronic hybrid devices.
